

# Atypical response of class IC atrial flutter to adenosine

## Risposta atipica alla adenosina di un flutter atriale classe IC

**ABSTRACT:** Atypical response of class IC atrial flutter to adenosine. F. Rotondi, T. Lanzillo, F. Manganelli, F. Lanni, F. Alfano, G. Stanco, G. Rosato.

We report the case of a 67-year-old female with a wide QRS complex tachycardia at 180 bpm.

A diagnosis of class IC atrial flutter with aberrant ventricular conduction caused by flecainide therapy was formulated. Intravenous adenosine administration resulted in adequate slowing of the ventricular rate and normalization

of QRS complexes. Restoration of sinus rhythm was achieved with intravenous amiodarone. The response to adenosine confirmed the diagnosis of supraventricular tachycardia with aberrant conduction, but the transition from arrhythmia onset to restoration of sinus rhythm showed interesting peculiarities.

**Keywords:** adenosine, class IC atrial flutter.

### Introduction

Class IC antiarrhythmic drugs are known to have the potential to convert atrial fibrillation to atrial flutter, probably by slowing isthmus conduction and/or limiting transverse conduction along the crista terminalis. The incidence of the so-called "class IC atrial flutter" in patients receiving class IC agents for atrial fibrillation is about 3.5-20% [1].

Slow atrial flutter with 1:1 atrioventricular conduction associated with aberrant ventricular conduction in the setting of class IC antiarrhythmic drug use is not easily distinguishable from ventricular tachycardias. The patient history, the performance of vagal maneuvers and adenosine administration, an antiarrhythmic drug with potent negative dromotropic effects, may often facilitate the diagnosis.

### Case Report

A 67-year-old female was referred to our cardiology department with a well tolerated, sustained, regular, monomorphic wide QRS complex tachycardia at 180 bpm (fig. 1). The patient suffered from hypertension and recurrent persistent atrial fibrillation. She was on flecainide, nebivolol and enalapril.

On admission, her blood pressure was 140/90 mmHg with an oxygen saturation of 95%.

Laboratory tests were unremarkable, except for elevated glucose (158 mg/dl; normal range 70-110 mg/dl) and urea levels (47 mg/dl; normal range 15-45 mg/dl).

Echocardiography showed mild left ventricular hypertrophy, normal systolic function (left ventricu-

lar ejection fraction 60%), and mild mitral regurgitation.

The clinical picture prompted us to consider the diagnosis of "class IC atrial flutter" with aberrant ventricular conduction caused by flecainide therapy. The patient was given an intravenous bolus of adenosine (6 mg), resulting in adequate slowing of the ventricular rate and normalization of QRS complexes (fig. 2). Restoration of sinus rhythm was achieved with intravenous amiodarone (0.5 mg/min) (fig. 3).

After two days, the patient was discharged asymptomatic on amiodarone 200 mg twice daily.

### Discussion

The response to adenosine was suggestive of supraventricular tachycardia with aberrant conduction. It is known that adenosine is both useful and safe as a diagnostic agent for the differential diagnosis of wide complex tachycardias [2], but in our case the transition from arrhythmia onset to restoration of sinus rhythm showed interesting peculiarities.

Following adenosine administration, a normalization of the QRS pattern was observed in the absence of any significant decrease in heart rate (fig. 4). It is likely that adenosine induced a slight prolongation of the cardiac cycle length, not detectable at 25 mm/sec, but sufficient to produce an improvement of the intraventricular conduction and a reduction in QRS duration [3].

Afterwards, the tachycardia tended to be persistent, showing alternating RR-intervals and alternating QRS complexes (fig. 5). The most reasonable

explanation for this “alternating” tachycardia is that it was due to dual atrioventricular nodal pathways with 2:1 block in the fast pathway resulting in alternating conduction along the fast and slow pathways.

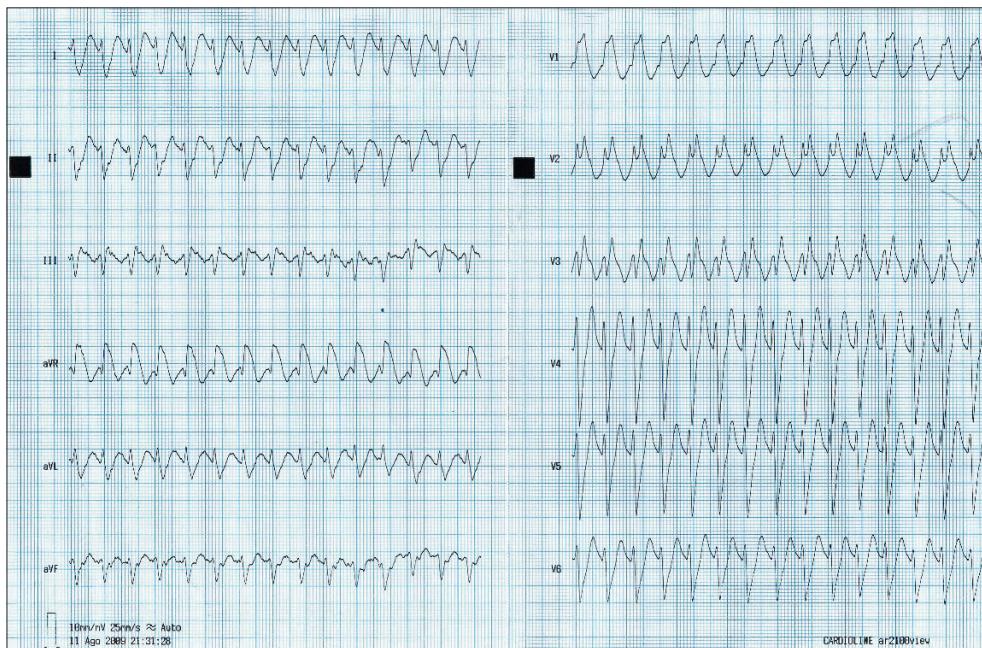

Figure 1. - Sustained, regular, monomorphic wide QRS complex tachycardia at 180 bpm.

The “electrical alternans” was elicited by cycle length alternation of RR intervals [4]. However, the alternating RR-intervals and QRS complexes may be due to decremental conduction through the atrioventricular nodal and His-Purkinje system. Unfortunately, the absence of an electrophysiological study, refused by the patient, can not confirm a dual atrioventricular nodal pathways.

The diagnosis of “class IC atrial flutter” was suspected upon the history of atrial fibrillation treated with flecainide and the ECG findings showing the typical features of aberrant conduction [5, 6]. Our patient did not meet the conventional diagnostic criteria for ventricular tachycardia, including atrioventric-

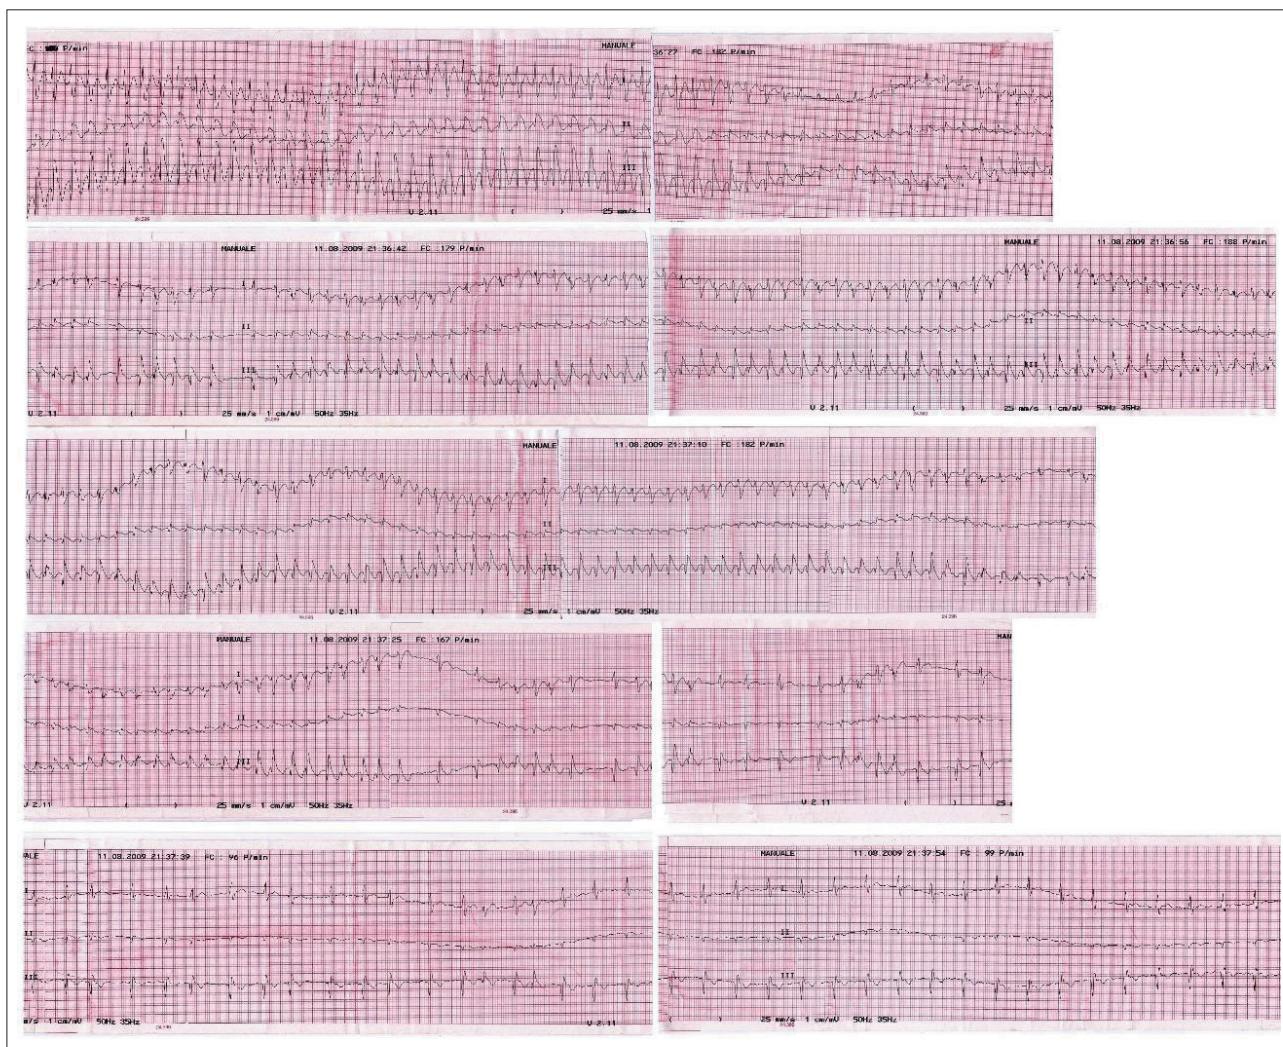

Figure 2. - Adenosine administration resulted in adequate slowing of the ventricular rate and normalization of the QRS complexes.

ular dissociation, second degree ventriculo-atrial block, capture or fusion beats, concordant precordial pattern, and an interval  $>100$  ms from the beginning of the QRS complex to the nadir of the S wave. QRS morphology during ventricular tachycardia showed a pattern of right bundle branch block with rR' in V1 and rSr' in V2, which was suggestive of aberrant conduction. The presence of rS complex in V6 is not a sign of ventricular ectopy when there is concomi-

tant extreme QRS axis deviation. A qR pattern in aVR with a q wave duration  $\geq 40$  ms is another typical diagnostic feature of aberrant ventricular conduction [7].

### Riassunto

*Riportiamo il caso di una donna di 67 anni con una tachicardia a complessi larghi a 180 bpm. Formulata la diagnosi di “flutter atriale IC” con aberranza di conduzione, causato dall’assunzione di flecainide, veniva somministrata adenosina ev, ottenendo la riduzione della frequenza ventricolare e la normalizzazione dei complessi QRS. Il ripristino del ritmo sinusale si otteneva dopo infusione ev di amiodarone. La risposta all’adenosina confermava la diagnosi di “flutter atriale IC” ma il passaggio dalla tachicardia iniziale al ritmo sinusale mostrava interessanti peculiarità.*

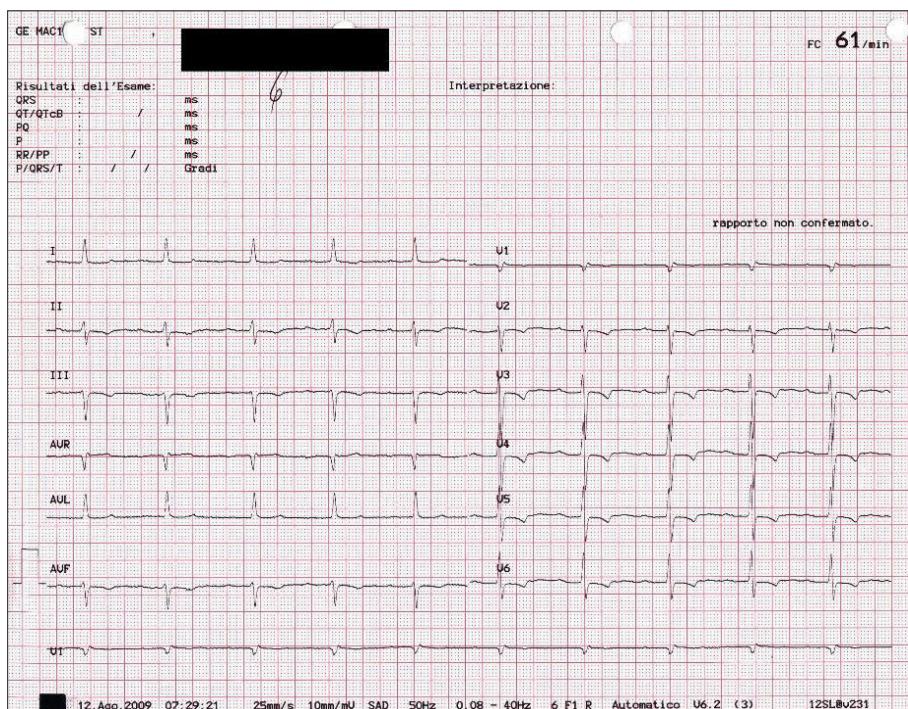

Figure 3. - Amiodarone administration resulted in restoration of sinus rhythm.

### ABBREVIATIONS LIST:

ECG: electrocardiogram

bpm: beats per minute

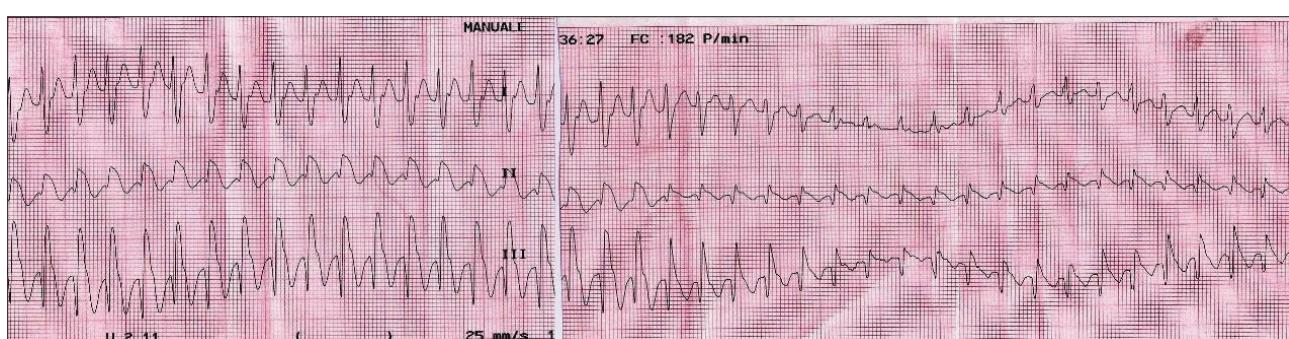

Figure 4. - Following adenosine administration, a transient and unexpected normalization of the QRS pattern was observed in the absence of any significant decrease in heart rate.

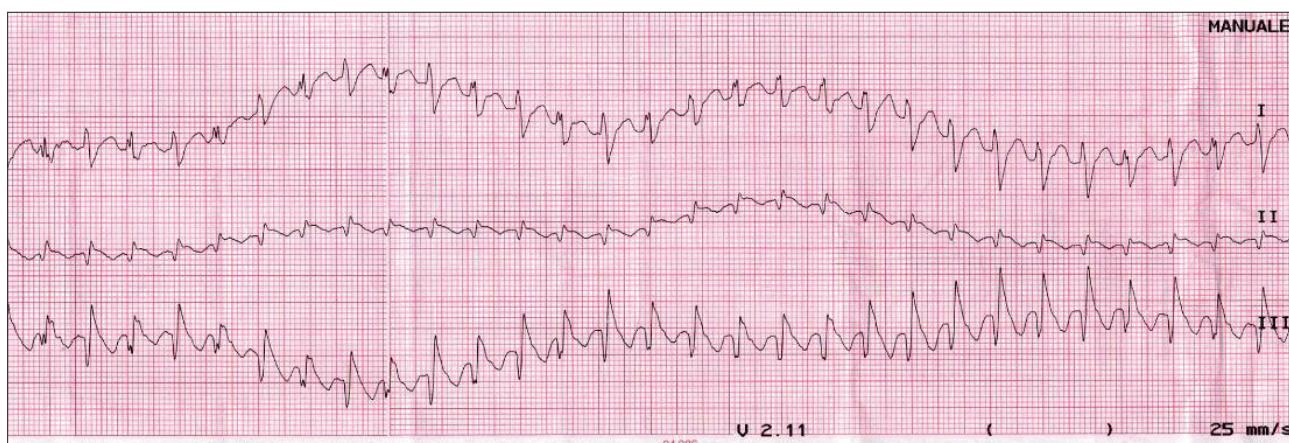

Figure 5. - Persistence of “alternating” tachycardia.
